

0:00–0:30 — Opening

“Good morning everyone. Today I’m presenting the Aero Home Manufacturing Performance Dashboard.

The objective of this dashboard is to give management and operational teams a single view of **production performance, quality, machine downtime, and supply-chain performance.**

Instead of looking at multiple Excel sheets or separate reports, this dashboard brings the important business KPIs into one place and also provides a validation page to make sure the reported numbers are reliable.”

0:30–1:30 — Page 1: Executive Dashboard

Point to the filters first.

“At the top, we have filters for **Plant, Supplier, Product, and Date.**

This allows a stakeholder to move from an overall company-level view to a specific plant, supplier, product, or period.”

Then explain the KPIs:

“For the selected period, the dashboard shows around **1.06 million units produced.**

The overall **production achievement is 96.29%**, which means actual production reached about 96% of the planned production.

The **defect rate is 1.70%**, so this gives the quality team an immediate indication of the proportion of defective units.

We also have approximately **122K downtime**, which helps operations understand the impact of machine or production interruptions.

Finally, the **supplier delay indicator is 16.55%**, which helps the supply-chain team monitor delivery-related issues.”

“So, in simple terms, these five KPIs answer five questions:

How much did we produce?

How close were we to our target?

How much quality loss occurred?

How much production time was lost?

And are suppliers supporting production on time?”

1:30–2:30 — Production & Operations

Point to the first row of charts.

Production Output by Plant

“This chart compares production output across the four plants.

This helps management identify differences in production volume between plants and investigate whether the difference is related to capacity, demand, downtime, or operational factors.”

Defective Units by Plant

“The next visual looks specifically at defective units.

This is important because a plant can have high production but also high defects. So production volume alone should not be used to judge performance.”

Downtime by Plant

“Here we can compare downtime across plants.

From a business perspective, downtime represents lost productive capacity. The operations team can use this information to investigate maintenance requirements, machine performance, or process interruptions.”

Then point to production trend:

“The production trend shows how output changes over time.

Instead of looking only at the yearly total, management can identify periods where production increased, decreased, or became unstable.”

2:30–3:15 — Supplier & Cost Perspective

Point to the bottom-middle charts.

“The dashboard also provides a supply-chain perspective.

The **Supplier Delay** visual helps identify suppliers with higher delivery delays.

The **Purchase Spend by Supplier** visual shows where procurement spending is concentrated.

Together, these two views are useful because we don't want to look at supplier cost and supplier performance separately.”

Strong business sentence:

“The objective is not simply to find the cheapest supplier; it is to understand the relationship between supplier cost, delivery performance, and production continuity.”

Then:

“This information can support procurement teams when they review supplier performance and future purchasing decisions.”

3:15–4:15 — Page 2: QA & Data Validation

This is where you impress the **technical stakeholders**.

Say:

“The second page is the QA and Data Validation layer.

The purpose of this page is different from the executive dashboard. The first page answers **‘What is happening?’**

This page helps answer **‘Can we trust the numbers?’**”

Excellent line. Pause after saying it.

Production & Operations Validation

“Here we validate production and operational KPIs at a more detailed level.

For example, the dashboard shows **18,093 defective units**, a **1.70% defect rate**, and **122,236 total downtime**.

We can also drill down into individual machines and employees to understand where these numbers come from.”

Quality Validation

“The quality section compares **planned units, produced units, production achievement, and defects** by plant and product.

For example, total planned production is **1,102,098 units**, while total produced is **1,061,194 units**, resulting in the reported **96.29% production achievement**.”

Supply Chain Validation

“The supply-chain section allows us to validate **purchase spend, supplier performance, material lead times, and delayed purchase orders**.

This provides more confidence that the high-level supplier KPIs are supported by detailed underlying data.”

4:15–4:45 — Business Value

Now stop talking about charts.

Say:

“From a business perspective, this dashboard provides three main benefits.”

1. Faster decision-making

“Management can see the important KPIs in one place instead of manually combining multiple reports.”

2. Early identification of problems

“Operations can identify high downtime, quality issues, production gaps, and supplier delays earlier.”

3. Data confidence

“The QA page provides detailed validation so that stakeholders can trace the high-level KPIs back to the underlying operational data.”

Then:

“So the dashboard is not only a reporting tool. It acts as a **decision-support and monitoring tool** for manufacturing operations.”

4:45–5:00 — Closing

Finish confidently:

“To summarize, the Aero Home dashboard connects four important areas of manufacturing performance: production, quality, operations, and supply chain.

The executive page provides a quick business view, while the QA and Data Validation page provides detailed verification of the reported numbers.

This helps stakeholders move from **‘What happened?’** to **‘Where did it happen?’** and then **‘Why should we investigate it?’**

Thank you. I’m happy to take any questions.”
